

notes on prototyping digital interactive stuff

Allison Parrish
IMA Capstone Studio

A prototype is “any representation of a design idea” that provide “the means for examining design problems and evaluating solutions.”

Houde and Hill 369, 368

Prototypes are "playable questions" that "turn ideas and concepts into something concrete that everyone on the team can evaluate" by "making ideas, motivations, and design values into tangible forms that can be played."

Macklin and Sharp, ch. 10

“How do I know what I think till I see what I [make]?”

–E.M. Forster, paraphrased

“Often the hands will solve a mystery that the intellect has struggled with in vain.”

–C. G. Jung

- Sometimes just sitting down with the *intention* to make a prototype is enough to solve a problem. As you're thinking through the steps needed to physicalize the problem, you'll often make a mental discovery that will obviate the prototype altogether.
- Prototypes help you figure out if you *like* the process of making the thing that you're setting out to make. They answer questions like, "Does this feel good? Do I want to keep working with these tools? Do I like investigating these ideas?" (This is especially important for Capstone students! You're going to be working hard on this, so you should *like* what you're doing!)

Macklin & Sharp's "iterative design process"

“[T]here is a difference between a game’s concept and a game’s design.... Turning an idea into a design requires that the designer structure the idea so that it can be used to produce prototypes, which are then playtested, the results of which are then evaluated to see what they say about the original idea...”

Macklin and Sharp, chapter 5

1. **Conceptualize:** Develop an idea for an interactive experience.
2. **Prototype:** Realize some aspect of the experience in a way that can be interacted with.
3. **Playtest** (or user test): Have people interact with the prototype and see what happens.
4. **Evaluate:** Review results and adjust concepts accordingly. Then return to step 1.

“The best way to figure out” how an interactive experience “will look, feel, and act is to dive in and start making it. The faster the [it] moves from the pure ether of ideas and into a prototype, the closer the [it] will get to showing the kind of play experiences it can generate. The key to prototyping is to turn the most promising ‘what if...’ question from the brainstorm, or a combination of ‘what ifs,’ into something tangible. That could be paper, quick and dirty code, even the designer’s own body...”

Macklin and Sharp, ch. 5

playtesting/user testing

- This will vary greatly depending on your project and on the prototype in question.
- The purpose is to see whether or not the approach in the prototype worked.
- Macklin and Sharp: “Playtesting is often the hardest and most revealing part of the iterative game design process. Often, what seems like a great idea that makes sense in a prototype falls apart when players get ahold of it. This might feel like a bad thing, but it’s really a blessing in disguise.”
- You might be your own playtester/user tester! Your project may not have “users” (or “players”), or you may at times need to short-circuit proper testing and just imagine yourself in the role of your audience.

evaluating the prototype

- Macklin and Sharp: Evaluation is “taking what playtesters did and said and determining if and how the feedback necessitates changes to the game’s design. [...] It takes practice, kind of like a doctor hearing a patient talk about their symptoms and then from that, building up enough evidence to make a diagnosis. It involves not only listening to what the patient says, but observing them and including all of that into the evaluation.”
- This can be qualitative, quantitative, or totally subjective. If it’s an art project, your “evaluation” might just be making a determination for yourself about whether or not the prototype in question produces the experience you’re after.

prototype technique and process

- Prototypes are *disposable*. They don't have to look "finished" (unless the "finish" is what you're prototyping). In fact, "finish" can sometimes communicate the wrong thing: "Finished-looking (or -behaving) prototypes are often thought to indicate that the design they represent is near completion" (Houde and Hill 368).
- The prototyping process is *partial, concurrent* and *iterative*. "No single prototype [can] represent the design of the future artifact" at early stages of development (Houde and Hill 371). Prototype different aspects of the project in different ways. Make new prototypes after evaluating prototypes in the previous iteration.
- Prototypes don't need to use the same materials or techniques that you envision for the final project. "What is significant is not what media or tools were used to create [prototypes], but how they are used by a designer to explore or demonstrate some aspect of the future artifact" (Houde and Hill 368).

paper prototypes

- Paper prototypes have a ton of advantages and are a good first step even (especially?) for digital systems.
- Low cost and low effort
- Can be modified easily
- Disposable
- Afford visual and spatial thinking (you can spread them out on the table)
- Afford easy (in-person) collaboration

fake it 'til you make it

- You don't have to write the code behind some behavior in your project to see if the idea works. Play act and role play with non-code tools.
- One version of this: Wizard of Oz prototypes. "Wizard of Oz prototypes allow you to test functionalities that have not yet been implemented. The user only tests a simulation of the actual functionality. Instead of the real functionality, the "Wizard of Oz" pulls the strings in the background."
<https://www.designthinking-methods.com/en/5Testen/wizardofOzTE.html>

document your prototypes

- Document your prototypes, or else you won't learn from them.
- Keep a “lab notebook” (this can be written, video, photos; use a spreadsheet maybe?).
- “You want to make sure to document the questions your prototype is exploring. You also want to record what you are doing to answer those questions.... And you need to make sure you capture how you did it, so you can re-create the prototype if you need to” (Macklin and Sharp chapter 10).

kinds of prototypes

Houde and Hill's “dimensions” of prototypes

- Role: “the function that an artifact serves in a user’s life” and “what features are needed to support it.”
Examples: Storyboards, journey maps, visual mockups.
- Look and feel: “the concrete sensory experience of using the artifact” when the goal is to “present its functionality in a novel way”. Examples: UX wireframes, implementations of interface elements, etc.
- Implementation: “techniques and components through which an artifact performs its function.” E.g., writing code to see if a computational technique is viable, or testing out pcomp components, etc.
- Integration: “represent the complete user experience of an artifact”; Such prototypes “verify that the design is complete and coherent.”

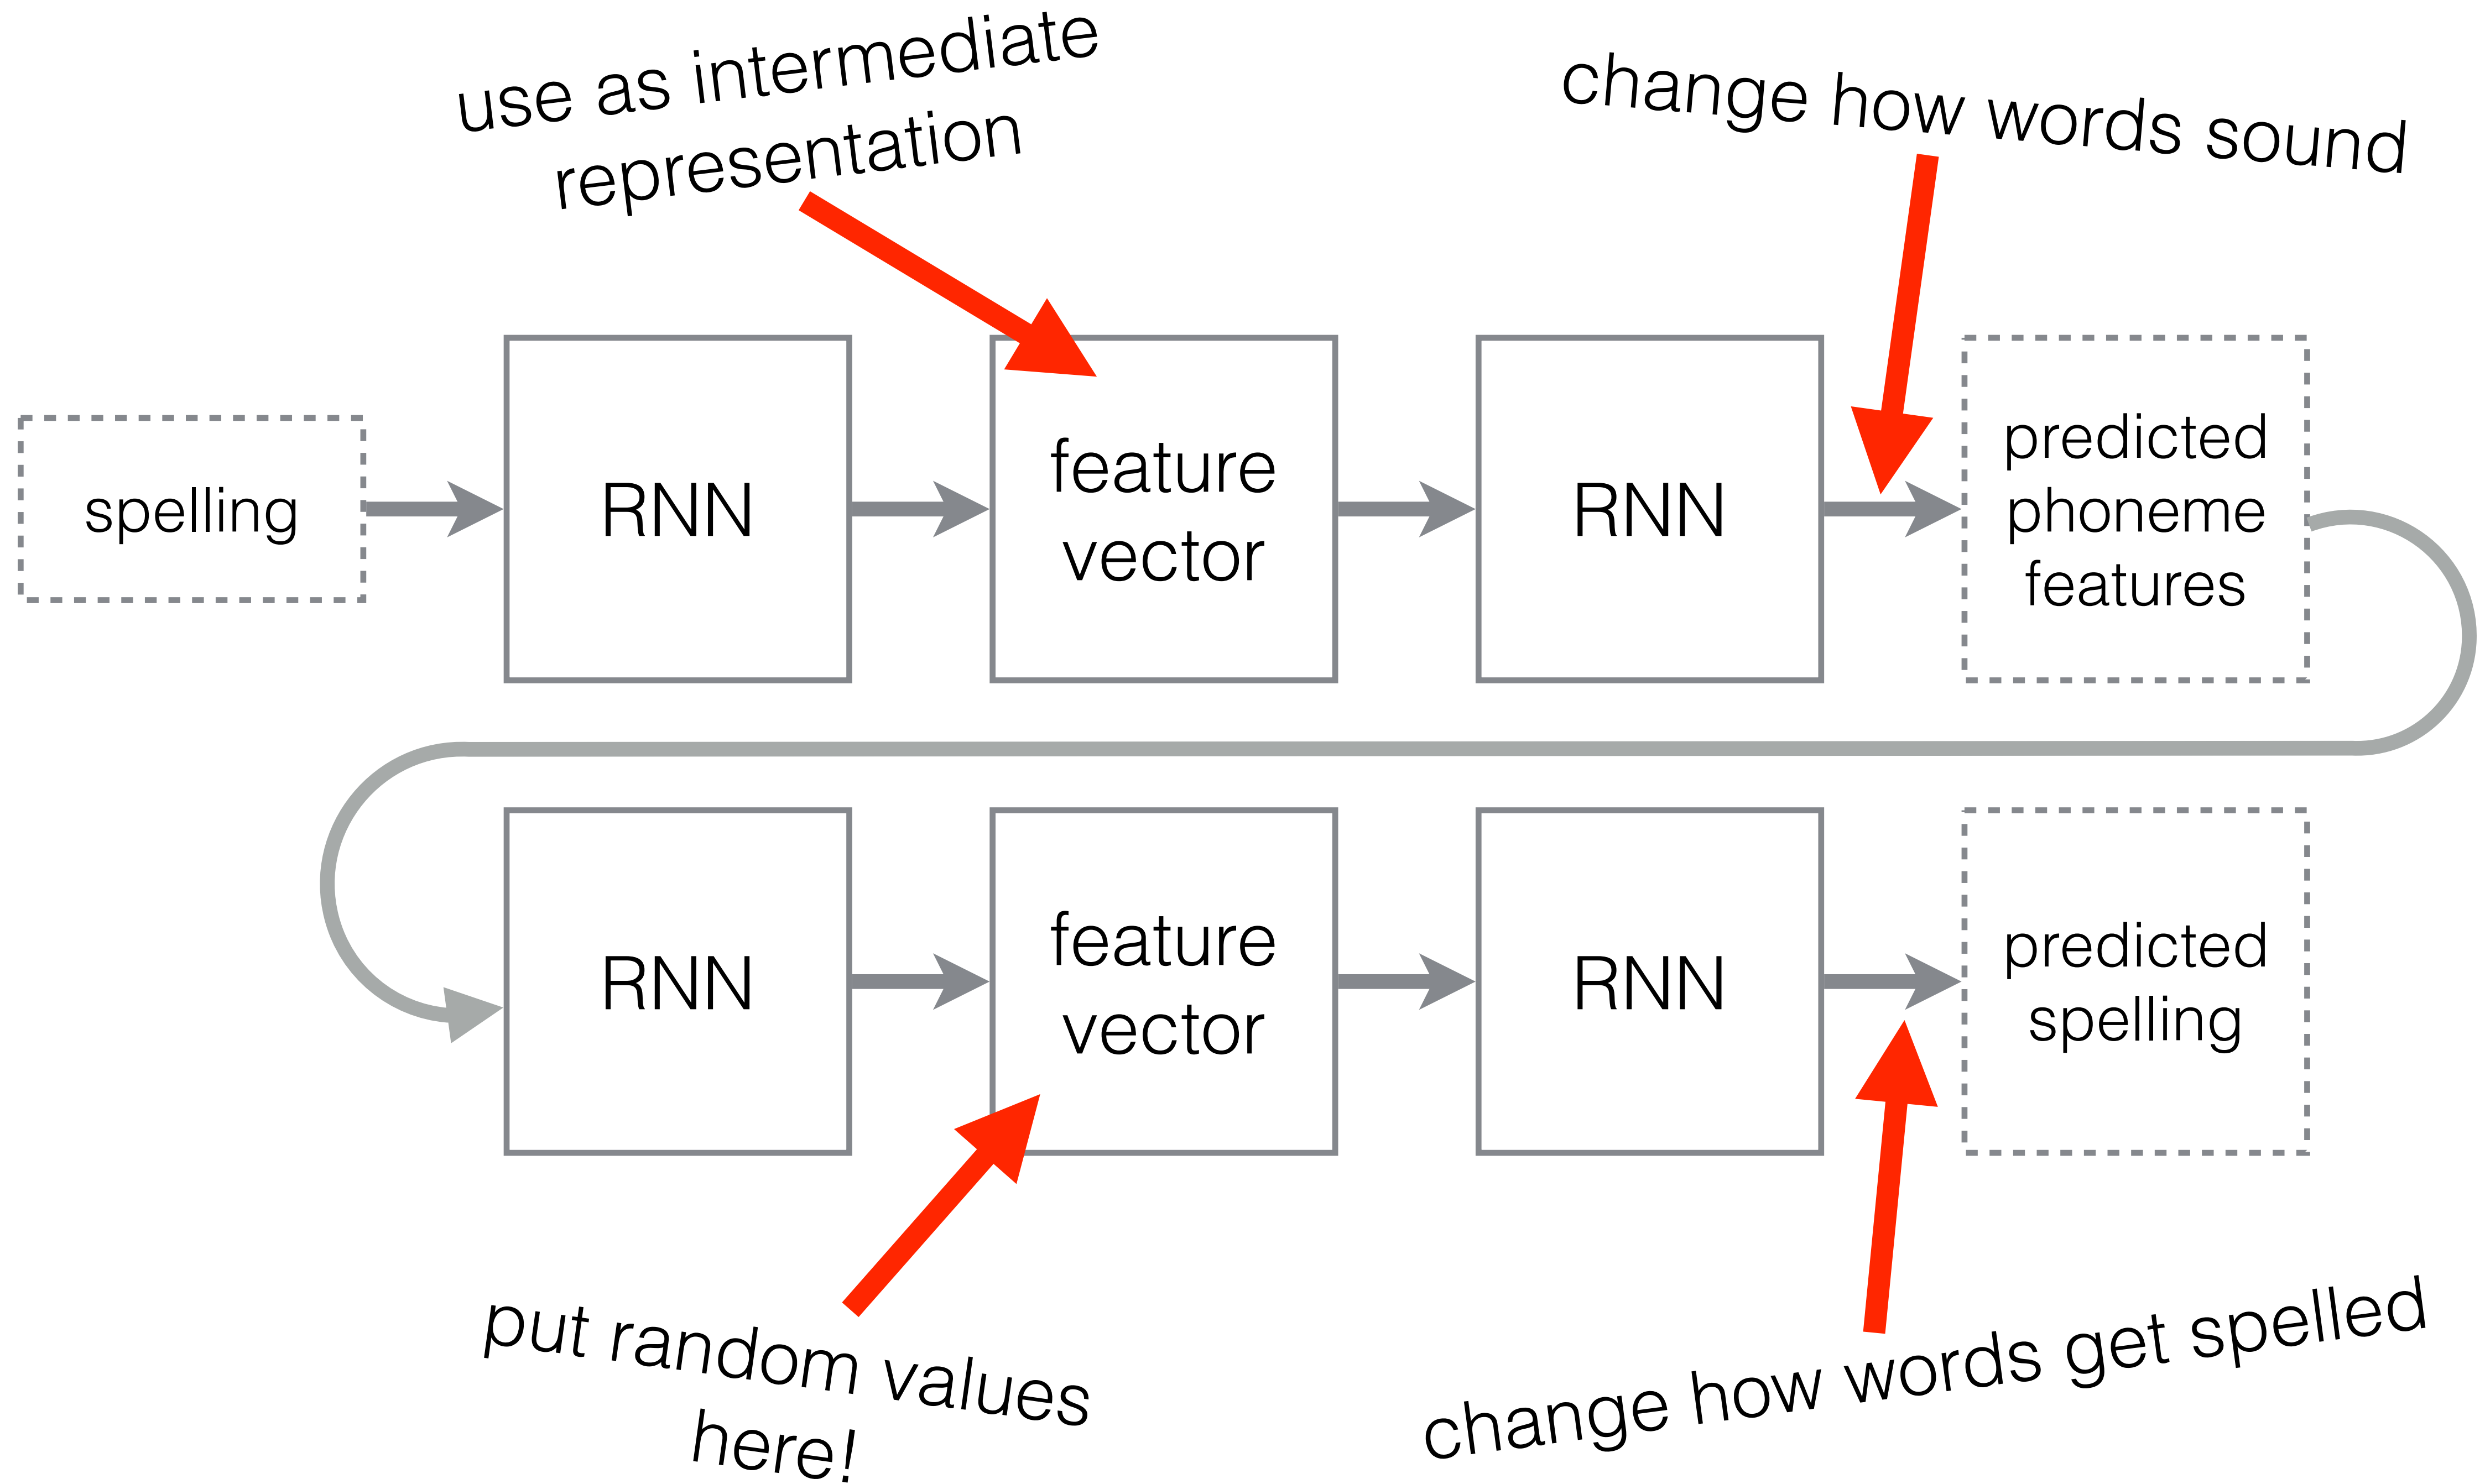

Macklin and Sharp's Prototype Categories

- **Paper:** Early stage for “making ideas concrete”
- **Physical:** “enacting aspects of the play experience in real life to help think through the play experience,” including role-playing
- **Playable:** “rough” prototypes, “often not including graphics, sound, or even goals” that investigate the “core actions,” implemented in such a way that the context of interaction is similar to that in the final project
- **Art and sound:** “exploring the visual and aural style, and sometimes, the production processes for creating these”
- **Interface:** “screen-based information and... feedback systems, but also the actual mechanism” that is used to interact with the project
- **Code/tech:** “technical aspects... like whether or not it will play smoothly on certain kinds of devices or computers”
- **Core game:** Like Houde and Hill’s “integration” prototype, these prototypes “move beyond the rougher playable prototype by including the full set of actions available” and perhaps “include basic art and sound” to evaluate their impact on the experience.
